Abstract

HuR is a ligand for nuclear mRNAs containing adenylate-uridylylate rich elements in the 3'-untranslated region. Once bound to the mRNA, HuR is recognized by adapter proteins which then facilitate nuclear export of the complex. In the cytosol HuR is thought to function to control stability and translation of its ligand message. In the 3T3-L1 cells HuR is constitutively expressed and localized predominantly to the nucleus in the preadipocytes. However within 30 min of exposure to the differentiation stimulus, the HuR content in the cytosol increases consistent with HuR regulating the availability of relevant mRNAs for translation. Using *in vitro* RNA gel shifts, we have demonstrated that the C/EBP β message is a ligand for HuR and that the single binding site is an adenylate-uridylylate rich element in the 3'untranslated region.

Keywords

CCAAT enhancer binding protein β ; HuR; elav; 3T3-L1; adipocyte; differentiation

Introduction

Adipocyte differentiation is a complex process regulated in large part by the temporally controlled expression and activation of numerous transcription factors [1]. Among these proteins, the C/EBP and PPAR families of transcriptional activators have been identified as critical to initiation of the differentiation process as well as maintenance of the adipocyte phenotype [1]. When growth arrested 3T3-L1 preadipocytes are induced to differentiate, the cells re-enter the cell cycle and undergo mitotic clonal expansion followed by cessation of growth and expression of the adipocyte phenotype [1]. During this process C/EBP β is expressed and is essential not only for mitotic clonal expansion but the transcriptional activation of PPAR γ and C/EBP α [2] and the indispensable nature of this carefully timed expression of C/EBP β has been demonstrated in several studies [3,4].

Messenger RNA export from the nucleus, mRNA turnover as well as translation initiation are important control points in the post-transcriptional regulation of gene expression. At least in part, control of these processes is exerted through recognition of *cis* elements in the mRNA by specific binding proteins. One of these binding proteins is HuR, which was first reported to bind to AU-rich elements in the 3'UTRs and is a 32-kDa protein belonging to the Hu/ELAV family (embryonic lethal, abnormal vision) of RNA binding proteins [reviewed in 5]. It is

localized predominantly to the nucleus but has been demonstrated to shuttle between the nucleus and cytoplasm [6,7] and suggested to function by binding to nascent mRNAs in the nucleus and protecting them from degradation by actively participating in their nucleo-cytoplasmic transport [6] as well as controlling their stability [8]. Thus, HuR appears to be an important regulatory protein that is involved in the posttranscriptional processing of certain mRNAs.

We have previously demonstrated that the C/EBP β mRNA is a ligand for HuR and that the formation of the complex may, in part, control the adipocyte differentiation process [9]. The identification of a HuR binding site in the C/EBP β mRNA was accomplished by inspection and use of the COVELS algorithm [10] which predicted a single HuR binding site between bases 1370 and 1386 of the 3'UTR. This region was confirmed to bind HuR through *in vitro* RNA gel shift analysis as well as immunoprecipitation of HuR containing messenger ribonucleoprotein particles and RTPCR analysis of the bound message [9]. This region exhibits a high A+U content and would be expected to serve as an adenylate-uridylylate rich element (ARE), conferring instability to the message [5]. However, a recent report demonstrated that HuR could function to mediate translocation of the CD38 mRNA from the nucleus to the cytosol through interaction with a structured RNA element that does not contain an ARE and is localized to the coding region of this message [11]. Based on this description of a novel HuR binding site coupled to a translocation function we initiated an examination of the entire C/EBP β mRNA for non ARE related HuR binding sites. The data presented support the existence of a single site in the C/EBP β mRNA for HuR binding corresponding to the ARE in the 3'UTR.

Materials and Methods

Materials

Dulbecco's modified Eagle's medium (DMEM) was purchased from Gibco/Invitrogen (Grand Island, New York). Bovine calf serum and fetal calf serum were purchased from Hyclone Laboratories (Logan, Utah). The 3T3-L1 cells used in this work were obtained from Howard Green (Harvard University, Boston, MA). The BCA Protein Assay kit, the NE-PERTM Cell Fractionation kit and HALTTM protease inhibitor mix were from Pierce (Rockford, IL). The MaxiScript T7 kit was from Ambion (Austin, TX). The anti-HuR monoclonal antibody was obtained from Santa Cruz Biotechnology (Santa Cruz, CA) and the anti-Armenian-Syrian hamster monoclonal antibody was obtained from BD Pharmingen (San Diego, CA). The cDNA for C/EBP β was obtained from Stephen Farmer (Boston University, Boston MA). Reagents for molecular biology were purchased from Invitrogen (Carlsbad, CA). All other chemicals were of reagent grade and purchased from Sigma-Aldrich Biochemical (St Louis, MO).

Methods-3T3-L1 cell culture

3T3-L1 preadipocytes were cultured, maintained and differentiated as previously described [12].

Isolation of cytosolic and nuclear fractions

The NE-PERTM Cell Fractionation kit was used to isolate cytosolic and nuclear fractions from the 3T3-L1 cells as per manufacturer's (Pierce) instructions with minor modifications as previously described [9]. The isolated fractions were stored at -80°C until use.

PCR isolation of regions within the C/EBP β cDNA

Bases 1 through 314 of the cDNA were isolated using the following primers: Forward 5'-GCCCGTTGCCAGGCGCCGCTTATAAA-3' and Reverse 5'-GGCTCCAGGTAGGGGCTGAAGTCGA-3'. Bases 288 through 642: Forward 5'-

TCGACTTCAGCCCCTACCTGGA-3' and Reverse 5'-GACAGGCTGCCGCTGCTG-3'. Bases 625 through 957: Forward 5'-CAGCAGCGGCAGCCTGTC-3' and Reverse 5'-GCTTGAACAAGTTCCGCAGGTG-3'. Bases 940 through 1254: Forward 5'-TGCGGAACCTGTTCAAGCA GC-3' and Reverse 5'-AGTTACACGTGTGTTGCGTAGTCC-3'. Bases 1179 through 1292: Forward 5'-TCGGGACTTTGATGCAATCC-3' and Reverse 5'-AACATCAACAACCCCGCAG-3'. Bases 1230 through 1500: Forward 5'-GGACTACGCAACACACGTGTAAC-3' and Reverse 5'-TTCTCGAGCGGATCCTTTGGCTTT-3'. The T7 polymerase binding site was included in double stranded templates used in the preparation of riboprobes for RNA gel shift reactions by including the sequence: 5'-GGATCCTAATACGACTCACTATAGGGAGCT-3'.

RNA gel shift analysis

Radiolabeled riboprobes were prepared using the Ambion Maxi-Script T7 kit as per manufacturer's instructions and used in RNA gel shift assays as we have previously described [9]. When supershifts were performed either anti-Armenian-Syrian hamster IgG or anti-HuR 3A2 monoclonal antibody (2 μ l) was added to replicate samples after the binding incubation and the incubation continued for an additional 30 min at room temperature. The anti-hamster IgG antibody was used as a specificity control.

Results and Discussion

We first examined the 5'UTR and coding region of the C/EBP β clone for the formation of complexes with cytosolic or nuclear proteins. The data presented in Fig. 1A indicates that complex formation with cytosolic derived proteins was not detected using RNA probes corresponding to bases 1 through 314 (lanes 1–3), bases 288–642 (lanes 4–6) or bases 625 through 957 (lanes 7–9). Lanes 10–12 demonstrate our ability to detect protein-RNA probe complex formation using a probe corresponding to our previously described [9] HuR binding site (lanes 10 and 11) and identify the protein component as HuR using the anti-HuR antibody (lane 12). Fig. 1B examines binding using nuclear derived protein. The data displayed in Fig. 1A & B indicate that complex formation does not occur between either cytosolic or nuclear protein and the 5'UTR or coding region of the C/EBP β mRNA.

The 3'UTR was isolated as three sections and the binding of both nuclear and cytosolic protein examined in a series of RNA gel shifts. The data displayed in Fig. 2, indicate that all three regions: bases 940 through 1254, lanes 1–3; bases 1179 through 1292, lanes 4 through 6 and bases 1230 through 1500, lanes 7–9, form complexes with protein from both nuclear and cytosolic compartments as indicated by a significant shift (lanes 2,3,5,6,8,9) relative to the probe alone (lanes 1,4,7). In Fig. 3A, RNA gel shifts were repeated using the same probes and cytosolic protein and supershifts were performed using the anti-HuR 3A2 monoclonal antibody (lanes 3, 6, 9). Only the probe corresponding to bases 1230–1500 generated a supershift (lane 9). This is consistent with HuR binding to the region between 1230–1500 which would correspond to the previously described ARE that serves as the HuR binding site [9]. Fig. 3B repeats the same experiment using nuclear protein and yields results identical to those observed with cytosolic protein. Only the most 3' region of the message contains a HuR binding site.

To further investigate/confirm that the protein complexes formed with the C/EBP β 3'UTR involved HuR, the previously described binding experiments were repeated and complexes crosslinked using a Strategene UV-Stratalinker, digested with a combination of RNase A and T1 and analyzed for molecular size by SDS-PAGE. The results shown in Fig. 4 demonstrate that the digestion process degrades the probes corresponding to regions 940–1254 and 1179–1292 with no protection of specific regions of the probe by binding proteins. Compare probe alone (lanes 1, 4, 7) with the digest after crosslinking (lanes 2, 3 and 5, 6 and 8,9). Only in the most 3' fragment (bases 1230–1500) did both nuclear and cytosolic protein protect regions of

the probe from RNase degradation (lanes 8, 9 relative to lane 7). The bands observed in lanes 2 and 3 as well as 5 and 6 appear identical to lanes 1 and 4 respectively, suggesting that they represent limit digests of the probe alone and not protected fragments. As expected based on previous work [9] HuR at 36 kDa was present in both nuclear and cytosolic extracts and capable of complex formation. Cytosolic proteins of 66, 76 kDa also bound this region of the C/EBP β mRNA while complexes with a protein of 89 kDa were weakly observed using both nuclear and cytosolic proteins for the assay. These observations suggest that multiple proteins are involved in complex formation in the distal region of the 3'UTR, particularly once the message is in the cytosol.

The data presented in the current study are consistent with: 1) HuR binding to the ARE present in the regions 1230–1500 and 2) that no other HuR binding site exists within the message. Thus, functional regulation mediated by HuR binding to the C/EBP β mRNA must be mediated through this one binding site.

Acknowledgements

We gratefully acknowledge the computational assistance provided by the laboratory of Dr. Jack Keene, Duke University Medical School for performing the analysis of the C/EBP β mRNA using the COVELS software package. We further acknowledge support for the performance of these studies provided by: NIH grant DK55169, ADA grant 7-03-RA-76 and a grant from The Brody Brothers Foundation MT7753.
