Introduction: We present an unusual presentation of a 39-year-old man with myalgias and shortness of breath.

Chief complaints: The patient presented to the emergency department with complaints of myalgias, shortness of breath and palpitations. During this hospitalization, he had multiple episodes of tachycardia and desaturation. The patient had elevated troponins and creatinine kinase. Differential diagnosis included pericarditis, pneumonia and malignancy.

Investigations: The patient had elevated ferritin and erythrocyte sedimentation rate.

Outcome: The patient had adult Still's disease.

Lesson: This case shows how the presentation and symptom complex of Still's disease together with the lack of specific serological markers can misguide the diagnosis.

Keywords: adult Still's disease, rheumatology, hemophagocytic lymphohistiocytosis, immunology

Introduction

We present an unusual case of a 39-year-old man who presented to the emergency department with myalgias, shortness of breath, palpitations and fever with chills. During this hospitalization, he had multiple episodes of tachycardia and desaturation. The patient had elevated troponins and creatinine kinase. Differential diagnosis included pericarditis, pneumonia and malignancy. The patient had elevated ferritin and erythrocyte sedimentation rate (ESR). This case shows how the presentation and symptom complex of Still's disease together with the lack of specific serological markers can misguide the diagnosis. Early recognition of the florid manifestations will shorten hospital stay and avoid putting the patient through a battery of tests.

Case

A 39-year-old African-American man with a past medical history of type 2 diabetes mellitus and hyperlipidemia presented with stiffness, generalized myalgias, shortness of breath and irregular heart beat. The patient reported that the symptoms had progressively worsened since onset (~1 week prior), which prompted him to seek emergent/urgent medical care at the outside hospital. Here, he was treated for statin-induced rhabdomyolysis with ibuprofen, valium and vicodin and discharged home. After 3 days, he presented to our hospital with persistent and worsening myalgias (that were 4/10 in intensity). He also complained of stiffness that was more prominent in lower extremities, neck, shoulders and chest. Upon further history, he reported decreased oral fluid

intake and 3-day history of dyspnea on exertion. Medication history was significant for discontinuation of statins 2 months ago. Review of symptoms was positive for non-productive cough of 2 weeks duration, fatigue and nausea. He denied experiencing similar symptoms in the past, recent travel or consumption of any over-the-counter or herbal medications. Past medical history included diabetes mellitus (diet controlled), hyperlipidemia and regular alcohol use (2 beers per day). Review of systems was positive for intermittent fever, trouble swallowing and flank pain. On examination, he was febrile (temperature 39.5°C), tachycardic (116 bpm), tachypneic (30 cpm) and hypoxemic (requiring 4 L of oxygen to maintain oxygen saturation >90%). Diffuse tenderness was elicited in majority of the proximal muscle groups. He also had right parasternal chest tenderness and mild bilateral lower extremity swelling. Initial investigations showed a white cell count of 10.5 (absolute neutrophil count 9.4), normal basic metabolic panel, negative gram stain of urine, negative respiratory virus panel, normal procalcitonin and creatinine kinase of 208. Based on initial evaluation, he was given a preliminary diagnosis of pneumonia and was started on 1 L of normal saline, intravenous antibiotics (ceftriaxone and azithromycin) and 4 L of oxygen via nasal cannula to keep his saturation >92%. Infectious workup revealed a negative sepsis screen, sputum, urine cultures, mononuclear test and normal lactic acid. He continued to have high spiking fevers, arthralgia, persistent tachycardia, chest pain worsened with deep breathing and cramps in bilateral lower extremities. On further investigations, he was found to have elevated troponins and creatine kinase. Imaging performed to further evaluate the cause for shortness of breath included a negative chest X-ray and computed tomography angiography (CTA) chest concerning multilobar pneumonia. As this was consistent with sepsis, he was continued on ceftriaxone and azithromycin for community-acquired pneumonia. Pericarditis was ruled out with transthoracic echocardiogram, which showed normal cardiac function and absence of any effusions. Tachycardia was thought to be likely due to anxiety and was managed with alprazolam 2 mg/pro re nata (PRN) or as needed. Infectious and autoimmune etiology were ruled out by the following tests: hepatitis panel, human immunodeficiency virus antibody, Epstein–Barr virus, mycoplasma antibodies, anti-nuclear antibodies, anti-neutrophil cytoplasmic antibodies, rheumatoid factor and anti-Jo-1 antibodies were negative. Elevated ferritin at 27,088 ng/mL, ESR at 105 mL/hour and C-reactive protein (CRP) at 344 µg/L were found. Patient continued to have persistent fevers. The search for a non-infectious etiology to explain the fever was sought out on day

6. Head and chest along with abdominal/pelvic CT showed no infectious etiology or evidence of malignancy. Hemophagocytic lymphohistiocytosis (HLH) can cause a similar level of hyperferritinemia to adult Still's disease (ASD) and was ruled out by the absence of leukopenia, lymphopenia and granulocytopenia. Also to be noted was the bone marrow biopsy that did not show any signs of hemophagocytosis. The patient continued to have aching sternal pain and tachycardia, raising concern for myocarditis with friction rub. He continued to have inconsistent fevers, episodes of desaturation and chest pain. He was started on colchicine and ibuprofen with transition to oral antibiotics. Based on elevated ferritin levels, persistent fevers and the lack of infectious foci, a diagnosis of adult-onset Still's disease was made. This diagnosis was discussed among infectious disease, rheumatology, hematology–oncology and general medicine departments. It was confirmed by the fact that patient responded well to steroids. He was started on 1 mg/kg/day of prednisone with resolution of symptoms 2 days after start of therapy. The total length of stay was 9 days. The patient was scheduled for regular follow-up every 2 weeks. We continued tapering doses of prednisone with the goal of 10 mg/day at the end of 7 weeks. At the end of 8 weeks, the patient did not have any flares and complained of some mild joint pain occasionally. Over the next 3 months, the patient continued a maintenance dose of 10 mg prednisone daily. He was seen in follow-up visits and was doing well with no complaints or flares. He was then gradually transitioned to the disease-modifying anti-rheumatic drug (DMARD) anakinra. Written informed consent was received from the patient.

Discussion

This case highlights the florid manifestations and challenges in diagnosing Still's disease. A patient presenting with quotidian fevers, evanescent rash and various types of arthritis is the typical presentation of ASD or systemic juvenile idiopathic arthritis.¹ The etiology is currently proposed as a mix of genetic factors (human leukocyte antigen [HLA] – B17, HLA – B18, HLA – B35 and HLA – DR2) and infectious triggers (Rubella, Parvovirus B19, *Yersinia enterocolitica*).^{2–5} Still's is a rare disease (incidence of 0.16/100,000 persons) with bimodal age distribution between ages 15–25 and 36–46.⁶ The disease has 3 presentations: monophasic type, intermittent type, and chronic articular type. Major presenting symptoms are quotidian fever, evanescent salmon colored rash and oligo- or poly-arthritis for all 3 types.⁷ Myalgia occurs with fever spikes and can be severe and debilitating. One of the characteristic symptoms seen in Still's disease

is fusion of wrist joints. Other symptoms include a severe, non-suppurative pharyngitis (found in 69% of cases), hepatomegaly (12–45%), elevated transaminases (75%), abdominal pain (1–48%) and cardiopulmonary disease (30–40%) such as pericarditis, pleural effusions and transient pulmonary infiltrates. Rarely renal, ophthalmic and neural involvement is also observed. Laboratory abnormalities include elevation of CRP, ESR and serum ferritin. Aspartate transaminase (AST) and alanine transaminase (ALT) are elevated with the disease and are further elevated upon the use of non-steroidal anti-inflammatory drugs (NSAIDs) in the treatment. Hematologic manifestations include lymphocytosis with neutrophilia, normocytic normochromic anemia and thrombocytosis, microangiopathic hemolytic anemia, thrombotic thrombocytopenic purpura (TTP)–hemolytic-uremic syndrome (HUS) and disseminated intravascular coagulation (DIC). Diagnostic criteria of Still's disease are given in Table 1.^{8–11}

Monophasic type has a single flare of disease that lasts between weeks to months, and then the disease usually completely resolves. Intermittent type flares last between several weeks to 1 or 2 years with one or more disease flares, and this type completely resolves as well. Chronic articular type patients have a persistently active disease, which usually evolves from monophasic or intermittent type. Treatment options and classification of disease are given in Table 2.

Of the numerous complications of Still's disease, the most serious is HLH. HLH is a syndrome associated with excessive immune activation. Macrophages, natural killer cells and cytotoxic lymphocytes are excessively activated with inadequate or absent down regulation. HLH symptoms include hepatomegaly, lymphadenopathy, neurological manifestation

and rash. In the presence of HLH along with ASD, an attempt should be made to treat ASD provided the patient is stable, as the treatment of HLH involves drugs with many side effects including dexamethasone, etoposide, methotrexate and in some cases cyclosporine. In an unstable patient, therapy should be directed toward resolving HLH. It is also prudent to remember that NSAIDs used in the treatment of ASD are one of the potential triggers of MAS. MAS is a rare

Table 2 Classification of Still's disease and treatment options

Type	Clinical features	Treatment	Dosage
Mild disease	Fever, rash, arthralgia or mild arthritis	Start with NSAIDs alone. 20% respond to this alone. Add low-dose glucocorticoids if symptoms control is not achieved in 10–14 days. Only 20% respond to NSAIDs alone.	Naproxen 500 mg BD, ibuprofen 800 mg TD or QID. Reduce doses as symptoms resolve and continue for 2–3 months. No DMARDs
Moderate disease	High fevers, debilitating joint symptoms, internal organ involvement that is not life threatening or severe	Start with glucocorticoids to control symptoms and inflammatory response. Responds within hours to few days. DMARDs for long-term management or when symptoms recur or cannot be controlled on tapering glucocorticoids. 70% respond to glucocorticoid alone.	Prednisone 0.5 mg to 1 mg/kg. Rapidly taper and maintain at low dose for 2–3 months even when symptoms are controlled. DMARDs anakinra for primarily systemic disease. Methotrexate for primarily articular disease. Taper after patient is stable for 4–6 months starting with glucocorticoid and then DMARD.
Severe disease	Life-threatening organ involvement and/or severe hepatic involvement, cardiac tamponade, DIC	Start with high-dose pulse glucocorticoids and anakinra. Add methotrexate in patients who have ongoing arthritis or develop erosive arthritis. Consider prophylactic antibiotics for pneumocystis pneumonia.	Methylprednisolone 1,000 mg intravenous daily for 3 days. Followed by oral prednisone 60 mg and anakinra 100 mg subcutaneous daily. Taper prednisone as tolerated with the goal of discontinuing it in 2–4 months

Table 1 Diagnostic criteria of Still's disease

Five of the following criteria should be met for a diagnosis of ASD. Two criteria must be major

Major criteria

1. Fever of at least 39°C (102.2°F) lasting at least 1 week
2. Arthralgias or arthritis lasting 2 weeks or longer
3. A non-pruritic macular or maculopapular skin rash that is salmon-colored in appearance and usually found over the trunk or extremities during febrile episodes
4. Leukocytosis (10,000/μL or greater), with at least 80% granulocytes

Minor criteria

1. Sore throat
2. Lymphadenopathy
3. Hepatomegaly or splenomegaly
4. Abnormal liver function studies, particularly elevations in AST, ALT and LDH concentrations
5. Negative tests for ANA and RF

Abbreviations: ASD, adult Still's disease; AST, aspartate transaminase; ALT, alanine transaminase; LDH, lactate dehydrogenase; ANA, anti-nuclear antibody; RF, rheumatoid factor.

Abbreviations: NSAIDs, non-steroidal anti-inflammatory drugs; DMARDs, disease-modifying anti-rheumatic drugs; DIC, disseminated intravascular coagulation.

complication of ASD and falls within the spectrum of HLH. It is similar to HLH in manifestations, but it usually arises as a complication of ASD and fulfills Yamaguchi classification criteria for Still's disease.^{12–14}

Prognosis is generally good for patients suffering from ASD with 90% of the patients being able to perform daily activities even when they are suffering from chronic type disease. Immediate identification of ASD is very important. The presentation and complications of the disease are florid. High index of suspicion for the characteristic signs and symptoms will help in early identification and reduce a great amount of discomfort. We suggest a classification of the patient based on disease severity and immediate treatment to reduce the rate of complications. This presentation is unique with pneumonia, myalgias and tachycardia as prominent symptoms. As a result, a search for other possible etiologies explaining the patient symptoms was carried out. This illustrates the point that Still's disease with its complications is still a diagnostic conundrum in spite of well-researched diagnostic guidelines. Physicians should be aware of this kind of presentation with pneumonia and tachycardia.

International Medical Case Reports Journal

Publish your work in this journal

The International Medical Case Reports Journal is an international, peer-reviewed open-access journal publishing original case reports from all medical specialties. Previously unpublished medical posters are also accepted relating to any area of clinical or preclinical science. Submissions should not normally exceed 2,000 words or

4 published pages including figures, diagrams and references. The manuscript management system is completely online and includes a very quick and fair peer-review system, which is all easy to use. Visit <http://www.dovepress.com/testimonials.php> to read real quotes from published authors.

Submit your manuscript here: <https://www.dovepress.com/international-medical-case-reports-journal-journal>
